An adder is a digital logic circuit that is used to perform the addition of numbers. Adders are an integral part of computers and various electronic gadgets that require numerical computing. In electronic devices, an adder circuit is usually present inside the arithmetic logical unit. There are basically two types of adder circuits, namely, half adder and full adder. Both half adder and full adder circuits fall under the category of combinational logic circuits. Half Adder in Digital Logic A half adder is a simple digital logic circuit that adds up two one-bit binary numbers. The inputs of the half adder are given as input 1 and input 2. These are typically referred to as A and B. The two outputs of the half adder are known as sum and carry. These are generally denoted by the English alphabets S and C. There are basically four combinations of the two inputs that can be fed to a half adder. Truth Table for a Half Adder The truth table for a half adder that tends to establish a relationship between the inputs and outputs of the logic circuit by denoting the truth or falsity of the output in accordance with a particular combination of input is given as: Truth Table for a Half Adder Logical Expression for Sum A EX-OR B Logical Expression for Sum in a Half Adder Logical Expression for Carry A AND B Logical Expression for Carry in a Half Adder Implementation of Half Adder A half adder can be implemented simply with the help of two logic gates, namely, an AND gate and an exclusive-OR gate. The exclusive-OR gate takes A and B as inputs and outputs the sum, while the AND gate takes A and B as input and delivers carry as output. Implementation of Half Adder Full Adder in Digital Logic A full adder is a digital logic circuit that obtains the sum of three one-bit binary numbers. The inputs of the full adder are given as input 1, input 2, and carry-in. These are typically referred to as A, B, and C-IN respectively. The two outputs of the full adder are known as sum and carry-out. These are generally denoted by S and C-OUT. There are eight possible combinations of the three inputs of a full adder. Truth Table for a Full Adder The truth table for a full adder that tends to establish a relationship between the inputs and outputs of the logic circuit by denoting the truth or falsity of the output in accordance with a particular combination of input is given as: Logical Expression for SUM Sum = A' B' C-IN + A' B' C-IN' + A B' C-IN + A B C-IN = (1,2,4,7) Sum = C-IN (A' B' + A B) + C-IN' (A' B + A B') Therefore, Sum = C-IN XOR (A XOR B) Logical Expression for Sum in a Full Adder Logical Expression for C-OUT C-OUT = A' B C-IN + A B' C-IN' + A B C-IN = (3,5,6,7) Therefore, C-OUT = A B + B C-IN + A C-IN A comparatively simpler method to evaluate the boolean expression for carry is given as follows: C-OUT = A B + A C-IN + B C-IN (A + A') C-OUT = A B C-IN + A B + A C-IN + A' B C-IN C-OUT = A B (1 +C-IN) + A C-IN + A' B C-IN C-OUT = A B + A C-IN + A' B C-IN C-OUT = A B + A C-IN (B + B') + A' B C-IN C-OUT = A B C-IN + A B + A B' C-IN + A' B C-IN C-OUT = A B (C-IN + 1) + A B' C-IN + A' B C-IN C-OUT = A B + A B' C-IN + A' B C-IN C-OUT = AB + C-IN (A' B + A B') Therefore, C-OUT = AB + C-IN (A EX-OR B) Logical Expression for Carry in a Full Adder Implementation of Full Adder Using Half Adders A full adder can be implemented simply with the help of two half adders and an OR gate. The first half adder takes A and B as input to produce a partial sum. The second half adder takes C-IN and the partial sum generated by the first adder to produce the final sum. This final sum is denoted as S. The carry output produced by both the half adders is fed to an OR gate, which gives C-OUT as the final carry. Implementation of Full Adder Using Half Adders Using NAND Gates A full adder digital logic circuit requires a total of 9 NAND gates for its implementation. Implementation of Full Adder Using NAND Gates Using NOR Gates A full adder digital logic circuit requires a total of 9 NOR gates for its implementation. Implementation of Full Adder Using NOR Gates 1. UNIVERSITY OF BÖTswana FACULTY OF ENGINEERING AND TECHNOLOGY DEPARTMENT OF ELECTRICAL ENGINEERING DIGITAL ELECTRONICS (EEB 322) LAB 2: LOGIC GATES AND COMBINATIONAL CIRCUITS (HALF ADDERS AND FULL ADDERS) DATE OF LAB SESSION: 07 APRIL 2016 AUTHOR: BOSa THEOPHILUS NTSHOLE STUDENT ID: 201301848 2. 2 Table of Contents AIMOF EXPERIMENT.....3 INTRODUCTION.....3 MATERIALS USED IN THE EXPERIMENT.....4 THEORY.....5 a. The Full Adder.....6 PROCEDURE.....7 RESULTS.....8 DISCUSSION.....9 RECOMMENDATIONS.....9 CONCLUSION.....9 REFERENCES.....9 3. 3 AIM OF EXPERIMENT The main purpose of this experiment is to introduce the design of simple combinational circuits, in this case half adder and full adders. INTRODUCTION In this experiment, the understanding of logic gates is used to perform basic hardware functions. We will be looking at how binary addition may be implemented using combinational logic circuits. We will consider the half and full adder for this particular experiment. The half adder is the combinational circuit which consists of two inputs and outputs which performs the addition of two bits. The output variables produce the sum and carry due to the input variables being designated the augend and addended bits. Also, the combinational circuit that performs the three bit addition which are made up of two significant bits and the previous carry is known as the full adder. The full adder is made up of three inputs and two outputs and outputs are the sum and carry. Depicted below are the pictures of ideal half adder and full adder respectively; Figure 1: ideal diagrams for the half and full adders 4. 4 MATERIALS USED IN THE EXPERIMENT - C.A.D.E.T breadboard - 1 x 74LS08 Quad 2-input AND Gate - 1 x 74LS32 Quad 2 -input OR Gate - 1 x 74LS86 Quad 2- input XOR Gate - Jumper wires 5. 5 THEORY a. The Half Adder The half adder is combinational circuit that Adds together two, single bit binary numbers a and b (note: no carry input). It has the following truth table; By inspection of the truth table; Depicted below is the actual circuit diagram of half adder; U 1A 74 LS08D 1 2 3 74LS86D 1 2 3 U 3A Figure 2. ACTUAL CIRCUIT FOR HALF ADDER 6. 6 b. The Full Adder The full adder is a combinational circuit that Adds together two, single bit binary numbers a and b (with a carry input). The full adder has the following truth table; Such that; So; And; 7. 7 So that; Alternatively; Which is similar to previous expression except with the OR replaced by XOR. Below is the actual combinational circuit diagram for the full adder; U 1A 74LS08D 1 2 3 74LS86D 1 2 3 U 4A U 5A 74LS32D 1 2 3 c s x y x Figure 3: ACTUAL COMBINATIONAL CIRCUIT FOR FULL ADDER CIRCUIT PROCEDURE The 74LS08 Quad 2-input AND Gate and the 74LS86 Quad 2- input XOR Gate were used for the first part of the experiment. Both of them were placed on the breadboard and the power was wired and then grounded. The circuit was set up as in figure 2. The outputs were observed at the connected LED lights that were placed at the output terminals of the combinational circuit and results were tabulated. 8. 8 The circuit was then modified such that it is a full adder combinational circuit as in figure 3. Outputs C and S were then observed and recorded respectively. RESULTS a. Table showing results obtained for half adder INPUTS OUTPUTS X Y C S 0 0 0 0 1 1 0 1 0 1 0 1 0 1 1 b. Table indicating the obtained responses Of full adder combinational circuit X Y Z C S 0 0 0 0 0 0 0 1 0 1 0 1 0 1 0 1 1 1 0 1 0 0 0 1 1 0 1 1 0 1 1 0 1 0 1 1 1 1 9. 9 DISCUSSION A lot of time was consumed by arguments since each group was made up of six people per working station. Other parties did not come prepared, a lot of time was consumed by trying to figure out and understanding first the theory and methodology used to carry out the experiment so much time which we could have used to carry out the experiment had elapsed. Another thing that made the experiment almost impossible to perform was lack of space, our work station was over crowded because the space in the work station was limited. This is a concern because time and again we had to reconnect our circuits, more especially the combination circuit, due to coiling up of jumper wires which made it difficult to trace the connections. Also, most of the apparatus used was very old that after connections were made, in most cases no outcome was traced or found leading to spending much time trouble shooting and fault finding rather than just taking readings we are sure of. There was deflection in practical outcomes here and there basically due to reasons stated in the discussion. RECOMMENDATIONS The University Of Botswana Electrical Engineering Department should start ordering laboratory equipment that is up to date and the already existing laboratory materials should be services regularly more especially before students come into the laboratory. The servicing should be carried out by the laboratory technicians thoroughly and the Electrical Engineering Department should perform thorough inspections on the serviced lab equipment in order to check if they need to be replaced or not. Electrical engineering students should always come prepared to the laboratory session so that much time can be spent on the experiment rather than discussing first what exactly should be done. Each student should participate thus having a task that one is capable of performing because they would have prepared thoroughly for the lab session. More equipment should be available at the labs to avoid students over-crowding on one working station. CONCLUSION The know-how in design of simple combinational circuits was acquired perfectly through gate behavior observation and considerations. It was also found out that practical results recorded were corresponding to theoretical results so every practical observation matched its expectations thus the practical results were exactly the same as the theoretical results. The combination circuit connections were perfect and all the other connections that were made gave all the right.
